Development of New Simulation Algorithms and its Application to Protein Aggregates

Biomolecules such as proteins and peptides have complicated free-energy landscape with many local minima. The conventional canonical-ensemble molecular dynamics (MD) simulations tend to get trapped in a few of the local-minimum states. To overcome these difficulties, we have proposed new generalized-ensemble algorithms, such as replica-permutation method. We apply these methods to proteins and peptides and try to predict the native structures of proteins as in Figure 1.

We are also interested in protein aggregates such as spherical substances called oligomers and acicular substances called amyloid fibrils (Figure 2). These protein aggregates cause more than 30 kinds of diseases. For example, Alzheimer’s disease is thought to be caused by aggregated amyloid-β (Aβ) peptides. To overcome these diseases, it is essential to understand the aggregate genesis and disruption of Aβ peptides. We perform such MD simulations of oligomers and amyloid fibrils.

Selected Publications

1. Molecular Dynamics Simulations of Amyloid-β(16–22) Peptide Aggregation at Air–Water Interfaces

The formation of Aβ oligomers is accelerated at hydrophilic–hydrophobic interfaces, such as the cell membrane surface and air–water interface. To understand the effects of the interface on oligomerization at the atomic level, we performed MD simulations of aggregation of Aβ(16–22) peptides at air–water interfaces.\(^1\) First, 100 randomly distributed Aβ(16–22) peptides (Figure 3(a)) moved to the interface (Figure 3(b)). The high concentration of peptides then accelerated their aggregation and formation of antiparallel β-sheets. Two layers of oligomers were observed near the interface. In the first layer from the interface, the oligomer with less β-bridges exposed the hydrophobic residues to the air. The second layer consisted of oligomers with more β-bridges that protruded into water. They are more soluble in water because the hydrophobic residues are covered by N- and C-terminal hydrophilic residues that are aligned well along the oligomer edge. These results indicate that amyloid protofibril formation mainly occurs in the second layer.

2. Development of Replica Sub-Permutation Method for Efficient Molecular Dynamics Simulations

We proposed an improvement of the replica-exchange and replica-permutation methods, which we call the replica sub-permutation method (RSPM).\(^2\) Instead of considering all permutations, this method uses a new algorithm referred to as sub-permutation to perform parameter transition, as in Figure 4. The RSPM succeeds in reducing the number of combinations between replicas and parameters without the loss of sampling efficiency. For comparison, we applied the replica sub-permutation, replica-permutation, and replica-exchange methods to a β-hairpin mini protein, chignolin, in explicit water. We calculated the transition ratio and number of tunneling events in the parameter space, the number of folding–unfolding events, the autocorrelation function, and the autocorrelation time as measures of sampling efficiency. The results indicate that among the three methods, the proposed RSPM is the most efficient in both parameter and conformational spaces.
